

CONTEXT

Civic is software designed to manage the entire life cycle of ends and ends. The software was developed 25 years ago and has been updated over time to comply with highway code regulations. **A local police department, through Civic, can manage the entire station,** its staff, fines, payments, photographic evidence, document management and API integrations with external services.

A selection of the previous search field masks.

Different UI templates on different screens, with different buttons, activating similar functions.

Aligning teams, stakeholders and product vision.

ROLE

Within the client team, I held the role of **Product/Service Designer and Product Owner**. I am part of a consulting team together with a front-end developer and a back-end developer. Furthermore, in the client team, there were some developers and subject matter experts, whom I coordinated for the definition of the product roadmap.

I managed the backlog, assigned tasks, aligned internal and external stakeholders, and proposed activities through pre-sale activities and alignment of expectations.

I independently managed the relationships with the entire client team and with all the interested parties involved, including the owner of the client company.

CHALLENGES

- The complexity of the software, in continuous development for 25 years, is enormous. Modules range from personnel and fine management to payment management, photographic evidence, documents and API integrations with external services. There are over 700 search fields alone, spread across 45 screens and 13 modules;
- **The design was not coherent nor consistent:** features were added over time without a unified design guideline, resulting in inconsistent behavior and patterns;
- Lack of documentation: there was no developer documentation, no user manuals, and the project lacked a proactive roadmap. **Each stakeholder had their own vision** of the future of the product;
- Positive feedback from users: despite some limitations, such as the lack of a cloud version, users were satisfied with the product features, **which made the need for a redesign less urgent**;
- Limited UX skills: the client team lacked the necessary UX knowledge, requiring parallel training to enable autonomous decision-making for future updates;
- Time constraints: The initial three-month timeline required prioritizing key elements, such as information architecture, to ensure developers could proceed **efficiently and autonomously**.
